

**ABSTRACT**

[0020] An embodiment of the invention is a garden hoe with a novel blade to better enable a gardener to perform gardening related tasks. The blade includes two similarly shaped cutting portions engaged in a partially overlapping manner. The hoe according an embodiment of the invention operates, among other ways, parallel to the surface of the ground to cultivate, till, weed, or otherwise dig up. A gardener can rotate the hoe around its handle's longitudinal axis to alter the angle with which the blade contacts the ground to more effectively chop, edge, and move dirt depending on the requirements of the gardening task.
